Introduction

Whakataakinga

Every year in New Zealand over 2,000 people are treated for a cardiac arrest that occurs in the community. With only one in ten New Zealanders surviving to 30-days, death from cardiac arrest is our ‘silent toll’. It can happen to anyone of any age, including children.

We remain focused on reducing this toll through the delivery of quality care, but we can’t do it alone. We need all New Zealanders to help by knowing how to perform CPR and use a defibrillator (or AED). Survival is largely due to the quick actions of bystanders who initiate CPR and use an AED within the first few minutes of a cardiac arrest. Outcomes from out-of-hospital cardiac arrest (OHCA) are dramatically improved when a patient receives early CPR and defibrillation. The more people who know how to do CPR and have access to an AED in the community, the greater the chance of patient survival. For every minute without CPR or defibrillation, a patient’s chance of survival falls by 10–15 percent. We believe that community initiatives such as free CPR awareness training, Restart A Heart Day, CPR in schools, and the GoodSAM smartphone application will improve survival from OHCA.

Alongside the community, the ambulance service has a strong influence on outcomes. Out-of-hospital cardiac arrest is the most time-critical and time-dependent condition to which the ambulance service responds. We benchmark ourselves internationally on our resuscitation performance as it tests all aspects of our system of care, from the community response to advanced life support. Benchmarking requires measurement and our Aotearoa New Zealand cardiac arrest registry enables this.

This continuous measurement determines whether making changes improves patient outcomes, and identifies further steps for improvement.

We are very pleased to present the 2018 – 2019 Aotearoa New Zealand, National Out-of-Hospital Cardiac Arrest Registry Annual Report.

Dr Bridget Dicker

St John

Dr Andy Swain  
Medical Director  
Wellington Free Ambulance

Dr Tony Smith  
Medical Director  
St John
Cardiac arrest remains a considerable public health issue, with ischaemic heart disease being the second most prevalent cause of death in New Zealand.

Internationally, survival rates following out-of-hospital cardiac arrest (OHCA) are highly variable and can range from less than 6% to greater than 50%. Benchmarking survival from OHCA is a key measure of the clinical quality of an Emergency Ambulance Service (EAS) and is fundamental to making improvements in OHCA survival. Knowledge of New Zealand OHCA outcomes is a key driver to help identify and address areas for improvement in clinical care.

The data presented in this report is for all OHCA attended by the St John and Wellington Free Ambulance EAS in the period from 1 July 2018 to 30 June 2019.

The data presented in this report primarily relates to events that were either ‘attended’ or where there was a ‘resuscitation attempted’ by EAS personnel. ‘Attended’ refers to all OHCA where EAS personnel arrived at the scene regardless of whether or not a resuscitation attempt was made. ‘Resuscitation attempted’ refers only to those events where an attempt at resuscitation was made by EAS personnel.

Unless otherwise stated, all analyses exclude cardiac arrests witnessed by EAS personnel. In cases where it was not recorded whether the patient was an adult or a child, the patient was assumed to be an adult and was included in that category.

Unless otherwise stated, survival refers to survival to 30-days post cardiac arrest.

All population figures in this report are derived from either Statistics New Zealand population data or the Ministry of Health Primary Health Organisation (PHO) enrolment data¹.
Executive summary

Five people a day (approx) were treated for an out-of-hospital cardiac arrest in New Zealand (more than 2,000 per year)

- 28% female,
- 72% male

76% of patients received bystander CPR

The median time in which an EAS ambulance reached a patient was 8 minutes in urban communities and 13 minutes in rural and remote communities

4% received defibrillation by a Community Responder prior to ambulance arrival

92% of events were co-responded to and attended by Fire and Emergency New Zealand

27% of patients survived the event (had a pulse on arrival at hospital)

14% of patients survived

All events, adult, resuscitation attempted: includes adults (≥ 15 years old), all-cause, resuscitation attempted. Excludes children, and EAS personnel witnessed events.

Benchmarking (all-cause events)
The outcomes of OHCA for international benchmarking compare rates of return of spontaneous circulation (ROSC) sustained to hospital handover and survival. This group requires that the following criteria be met: includes adults (≥ 15 years old), all-cause, resuscitation attempted. Excludes children, and EAS personnel witnessed events.

C New Zealand reports on survival to 30-days, all other services report survival to hospital discharge.
Benchmarking (Utstein Comparator Group)\textsuperscript{A}

The outcomes of OHCA for international benchmarking compare rates of ROSC sustained to hospital handover and survival for a specifically selected subgroup of patients. This subgroup is referred to as the Utstein Comparator Group and requires that the following criteria be met: includes adults (≥15 years old), all-cause, resuscitation attempted, shockable presenting rhythm and bystander witnessed. Excludes children, EAS witnessed and no resuscitation attempt.

---

**The age-adjusted incidence**  
**92.6** per 100,000 person-years

---

A. **All events, adult, attended**: includes adults (≥ 15 years old), all-cause, resuscitation attempted and no resuscitation attempted.  
   Excludes children, EAS personnel witnessed events.

B. **All events, children, attended**: includes children (< 15 years old), all-cause, resuscitation attempted and no resuscitation attempted.  
   Excludes adults, EAS personnel witnessed events.

C. Age-adjusted incidence was calculated using the New Zealand PHO enrolment data for quarter 3, 2013 (July to September 2013).
Men suffer OHCA at an earlier age than women, and women live longer than men. That is why men have a higher incidence of OHCA at almost every stage of life (Figure 2).
Ethnicity

The majority of OHCA events attended by EAS were for patients of European ethnicity, which reflects the NZ population demographics (Figure 3). When ethnicity-specific rates were evaluated, Māori and Pacific Peoples had a disproportionately higher incidence of OHCA compared with Europeans. Ethnicity-specific rates were calculated based on the New Zealand Ministry of Health prioritised ethnicity categories. Asian, Middle Eastern/Latin American/African, and Other Ethnicities combined made up less than 5% of cardiac arrests attended.

### Figure 3: Distribution of OHCA according to ethnicity

<tr>
<td>Pacific Peoples</td>
<td>109.3</td>
</tr>
</tbody>
</table>

*Figure 4: Ethnicity-specific incidence of OHCA per 100,000 person-years (all events, attended)*

---

A **All events, attended**: includes adults and children, all-cause, resuscitation attempted and no resuscitation attempted. Excludes EAS personnel witnessed events.

B Ethnicity-specific incidence rates are based on Primary Health Organisation (PHO) Enrolment Demographics 2019 Q3 (July to Sept 2019).
**Deprivation-specific rates**

The NZDep2013 is a measure of socioeconomic deprivation calculated using census data. Some of the factors included in this measurement of deprivation are: no access to the internet, receiving a means tested benefit, household income below an income threshold, being 18–64 years old and unemployed, being 18–64 years old with no qualifications, not living in own home, a single parent family, household bedrooms less than occupancy threshold and no access to a car. The NZDep2013 quintiles range from Q1–5, where the 20% least deprived areas are scored as Q1, and the most deprived 20% are scored as Q5. The incidence of OHCA increases as deprivation increases (Figure 5).

**Incidence across urban and rural/remote areas**

A larger proportion of the New Zealand population is based within metropolitan centres and consequently a greater portion of OHCA events occurred within metropolitan localities (71%). The incidence rate for the urban population was 84.1 per 100,000 person-years and for the rural/remote population was 118.8 per 100,000 person-years.

**Precipitating events for adults**

EAS personnel presume an OHCA to be of cardiac cause unless it is known or likely to have been caused by trauma, drowning, poisoning or any other non-cardiac cause. The most common aetiology of OHCA in adults where resuscitation was attempted was that of a presumed cardiac cause, which constituted 81% of events. (Figure 6).

**Precipitating causes for children**

The occurrence of OHCA in children is significantly less than in adults. During the period of this report, the leading cause of OHCA in children was respiratory arrest followed by Sudden Unexpected Death in Infancy (SUDI) (Figure 7).

**OHCA location**

The most common place for an OHCA to occur is in a person’s home, with 70% of events where resuscitation was attempted occurring at home. The second most common place for an OHCA to occur is in a public area (22%), which includes the workplace, the street, a shopping centre or similar (Figure 8).

---

A. **All events, attended**: includes adults and children, all-cause, resuscitation attempted and no resuscitation attempted. Excludes EAS personnel witnessed events.

B. **Deprivation calculation**: The NZDep2013 is a measure of socioeconomic deprivation assigned to a geographic area called a meshblock. The NZDep2013 quintile assigned to an event was derived from the incident location at the time of the event.
Precipitating causes for adults

- 81% Presumed cardiac
- 7% Respiratory
- 4% Hanging
- 3% Other non-cardiac
- 3% Trauma
- 1% Poisoning
- 1% Drowning

*Figure 6: Precipitating causes for adults (all events, adult, resuscitation attempted)*.

Precipitating causes for children

- 43% Respiratory
- 19% Sudden Unexpected Death in Infancy (SUDI)
- 13% Drowning
- 7% Presumed cardiac
- 7% Trauma
- 6% Hanging
- 4% Other non-cardiac

*Figure 7: Precipitating causes for children (all events, child, resuscitation attempted)*.

Location of OHCA

- 70% Home
- 22% Public
- 4% Other
- 2% Aged Care facility
- 2% Healthcare facility

*Figure 8: Location of OHCA for adults (all events, adult, resuscitation attempted)*.

**A** All events, adult, resuscitation attempted: includes adults (≥ 15 years old), all-cause, resuscitation attempted. Excludes children, and EAS personnel witnessed events.

**B** All events, child, resuscitation attempted: includes children (< 15 years old), all-cause, resuscitation attempted. Excludes adults and EAS personnel witnessed events.
**Outcomes Whakataunga**

**Adult outcome from all-cause cardiac arrest**
The results from the OHCA Registry show an event survival rate (ROSC sustained to hospital handover) of 27%.

The rate of survival to 30 days in adults where resuscitation was attempted was 14%.

**Utstein Comparator Group**
The international benchmarking of OHCA outcomes also compares survival rates for a specific group of patients. This subgroup is referred to as the Utstein Comparator Group and requires the following criteria to be met: includes adults (≥ 15 years old), all-cause, resuscitation attempted, shockable presenting rhythm, bystander witnessed and excluding EAS personnel witnessed events.

In the current reporting period, there were 588 cardiac arrests that met the Utstein criteria. This subgroup of patients represented approximately 30% of all events where resuscitation was attempted.

For this selected subgroup the rate of 30-day survival was 35%. This result is benchmarked against other services within the executive summary (Table 3).

---

A All events, adult, resuscitation attempted: includes adults (≥ 15 years old), all-cause, resuscitation attempted. Excludes children, and EAS personnel witnessed events.

B Utstein Comparator Group: includes adults (≥ 15 years old), all-cause, resuscitation attempted, shockable presenting rhythm and bystander witnessed. Excludes children, EAS witnessed and no resuscitation attempt.
Scene outcome for OHCA in adults
One of the contributing factors to patient survival is good quality chest compressions during CPR. Performing CPR during the transport of a patient following an OHCA may compromise the quality of the CPR being delivered. Therefore, in the majority of OHCA events, it is appropriate to continue resuscitation at the scene until either ROSC occurs or resuscitation is ceased. This is reflected in the scene outcomes observed in adult patients where resuscitation was attempted (Figure 9). The overall percentage of patients transported with CPR in place was 2%, transported with ROSC was 28% and died at the scene was 70%.

Adult outcomes according to presenting rhythm
Patients who present with a shockable rhythm such as ventricular fibrillation (VF) or ventricular tachycardia (VT) have a greater chance of survival than patients who present with a non-shockable rhythm such as pulseless electrical activity (PEA) or asystole (Figure 10).

EAS personnel witnessed outcomes
If a patient presents with a shockable rhythm and the arrest is witnessed by EAS personnel, the immediate intervention of defibrillation can lead to the best outcomes. Of the adult patients who had a shockable presenting rhythm where the arrest was witnessed by EAS personnel, the rate of event survival was 78% and survival to 30-days was 55% (not shown).

Outcomes according to age
New Zealand has an aging population. It is important to review whether outcomes vary with age. Those who were 80 and over at the time of their cardiac arrest had the lowest percentage survival compared to those who were younger (Figure 11).
Adult outcomes according to ethnicity
Rates of OHCA are higher in Māori and Pacific Peoples compared to European. Māori and Pacific Peoples had a lower 30-day survival than European (Figure 12). It is likely that there are greater differences in outcomes according to ethnicity. However, this data is only for a single year therefore the overall numbers of Māori and Pacific patients (n=432 and n=211 respectively) are small and thus may not be truly representative.

Adult outcomes according to deprivation
Incidence of OHCA increases with increasing socioeconomic deprivation. Compared to the least deprived quintile (Q1), those in the most deprived quintile (Q5) had lower 30-day survival (Figure 13).

Adult outcomes according to rurality
Incidents that occurred in rural locations also had lower event survival and 30-day survival than those that occurred in urban settings (Figure 14).

---

A All events, adult, resuscitation attempted: includes adults (≥ 15 years old), all-cause, resuscitation attempted. Excludes children, and EAS personnel witnessed events.

B Deprivation calculation: The NZDep2013 is a measure of socioeconomic deprivation assigned to a geographic area called a meshblock. The NZDep2013 quintile assigned to an event was derived from the incident location at the time of the event.
The community response is fundamental to improving outcomes from OHCA

**Adult outcomes according to GoodSAM responder presence**

GoodSAM (Good Smartphone Activated Medics) is a cell phone application that alerts community responders to nearby cardiac arrests (www.goodsamapp.org). Anyone who is trained in CPR and how to use an AED is able to register as a GoodSAM responder (https://youtu.be/EPwY3yGj8IY).

In 12% of all confirmed cardiac arrests a GoodSAM responder was present. When a GoodSAM responder was present both event survival and 30-day survival were increased compared to events where there was no GoodSAM responder (Figure 15).

**Adult outcomes according to defibrillation by Fire and Emergency New Zealand**

During this reporting period Fire and Emergency New Zealand personnel were present at 92% of adult OHCA events where resuscitation was attempted by EAS. When Fire and Emergency New Zealand or First Response Group defibrillation occurred prior to EAS arrival both event survival and 30-day survival were increased. Fire and Emergency New Zealand were fundamental in the early defibrillation of 169 adult patients in cardiac arrest, 22% of these survived to 30-days compared with only 11% that did not receive defibrillation prior to EAS arrival (Figure 16).

**Adult outcomes according to community defibrillation**

When community defibrillation occurred prior to EAS arrival both event survival and 30-day survival were increased. Community members were fundamental in the early defibrillation of 86 adult patients in cardiac arrest, 48% of these survived to 30-days compared with only 11% that did not receive community defibrillation prior to EAS arrival (Figure 17).

---

All events, adult, resuscitation attempted: includes adults (≥ 15 years old), all-cause, resuscitation attempted. Excludes children, and EAS personnel witnessed events.
Conclusion
Mutunga

The data presented in this report represent the 2018/19 results from the Aotearoa New Zealand National OHCA registry. They provide a substantive benchmark from which continuous improvements can be made.
Appendices

The Aotearoa New Zealand National Out-of-Hospital Cardiac Arrest Registry

The Aotearoa New Zealand OHCA registry is overseen by Prof. Bridget Dicker on behalf of St John and Wellington Free Ambulance. Prof. Dicker is Head of Clinical Audit and Research at St John and an Adjunct Professor at Auckland University of Technology (AUT), Department of Paramedicine.

Eligibility
The registry captures data on all OHCA events attended by EAS. A cardiac arrest is defined as a patient who is unconscious and pulseless with either agonal breathing or no breathing.

Inclusion and exclusion criteria are described in Table 4 and Table 5.

Data capture
The data is collated in the registry using a reporting template based on international definitions outlined in the Utstein style of reporting and the variables developed by the Australian Resuscitation Outcomes Consortium (Aus-ROC).

In the data collection process there are three separate points where data is acquired:
- Computer Aided Dispatch (CAD) and supporting systems
- On scene by the EAS personnel in attendance
- Mortality data from the New Zealand National Health Index (NHI) records.

Computer aided dispatch
Patient and event details are collected by the Clinical Control Centre when a 111 call is received and an ambulance is dispatched, with data being entered into the CAD system. Data specifically related to cardiac arrest is obtained from the CAD system and transferred into the OHCA Registry.

On scene collection
Ambulance officers on scene attending a patient in cardiac arrest are required to record specific data. This is recorded on an electronic Patient Report Form (ePRF) and submitted electronically to a secure server.

<td>Bystander suspected cardiac arrest where the patient is not in cardiac arrest on arrival of the EAS personnel, where defibrillation did not occur prior to ambulance arrival or no other evidence verifying a cardiac arrest state is present</td>
</tr>
</tbody>
</table>
NHI patient outcome data
The patient’s NHI is collected by EAS personnel on scene or at hospital handover. If the NHI was not available at the time of the event then the NHI is determined by cross-reference of the patient’s date of birth and name to the NHI database.

If a patient dies the date of death is updated by the Ministry of Health identity data management team after matching NHI identity with the official death registrations on a monthly basis.

Data quality
The registry is subject to quality improvement processes which involve continual auditing of existing data and updating of the registry entries as appropriate.

Registry reports are generated on a monthly and quarterly basis and these are analysed for variances in the numbers of cases and patient outcomes. These results are compared with international data from EAS that are similar to New Zealand.

Missing data
A period of industrial action occurred within the St John jurisdiction between December 2018 and July 2019. During this period there were 288 records that were transcribed manually into the electronic platform from paper records. It is unknown if there were additional records that went missing during this time. However, the total number of records within the registry is similar to previous years, therefore it is likely the amount of missing data is less than 5%.

These data do not include any patients from the Christchurch Mosque shootings that occurred on March 15th 2019.

Ethical review
The OHCA Registry has been approved by the New Zealand Health and Disability Ethics Committee (Ethics reference: 19/NTB/187).

The registry is also subject to EAS internal research governance processes that include a locality review and locality authorisation as per the Standard Operating Procedures for Health and Disability Ethics Committees.

The OHCA Registry is held on a secure server which requires active directory permissions. At no stage is data that could identify individual patients or individual hospitals released from this registry.

<td>Patients aged 15 years or older.</td>
</tr>
<tr>
<td>Asystole</td>
<td>The absence of any cardiac electrical activity.</td>
</tr>
<tr>
<td>Children</td>
<td>Patients aged less than 15 years.</td>
</tr>
<tr>
<td>Community responder</td>
<td>A member of the community who is not part of the EAS service who provides assistance at an OHCA event for example, a member of the public, or an off duty ambulance officer or an off duty doctor or nurse.</td>
</tr>
<tr>
<td>EAS attended</td>
<td>This is the population of all patients following cardiac arrest where EAS personnel attended regardless of whether emergency treatment was provided.</td>
</tr>
<tr>
<td>EAS personnel</td>
<td>Where EAS personnel respond to a medical emergency in an operational capacity as part of an organised medical response team.</td>
</tr>
<tr>
<td>Presumed cardiac aetiology</td>
<td>An OHCA is presumed to be of cardiac aetiology, unless it is known or likely to have been caused by trauma, drowning, poisoning or any other non-cardiac cause.</td>
</tr>
<tr>
<td>Resuscitation attempted</td>
<td>The performance of CPR by or under the direction of responding EAS personnel, or the delivery of a shock at any time (including before ambulance arrival).</td>
</tr>
<tr>
<td>Return of spontaneous circulation</td>
<td>The patient shows clear signs of life in the absence of chest compressions for more than 30 seconds. Signs of life include any of the following: Normal breathing, palpable pulse, normal end tidal CO₂, or normal movement.</td>
</tr>

Shockable rhythm

Ventricular fibrillation, ventricular tachycardia or unknown shockable (AED).

Specific rates

Rates for specific segments/groups of the population (e.g. sex, age, ethnicity).

Survival to 30-days

The patient is alive at 30-days post-OHCA event.

Survived event

The patient has sustained ROSC to handover at hospital.

Urban area

Includes:

- Main urban area: centred on a city or major urban area with a minimum population of 30,000.
- Secondary urban area: centred on large regional centres with a population between 10,000 and 29,999.
